The content is not tailored to your individual situation, knowledge, objectives, or risk profile.

The results presented may include historical simulations (backtests) and may not reflect all execution costs and constraints (including commissions, spreads, slippage, taxes, and liquidity limitations). Historical or simulated performance is not a guarantee of achieving similar results in the future.

Investing, especially in derivative instruments (e.g., futures, CFDs), involves high risk, including the risk of losing your entire invested capital and, in some cases, an obligation to provide additional margin.

These materials do not constitute an offer or solicitation to enter into any transactions. Do not copy the transactions or strategies presented. All investment decisions are made independently and at your own risk.

The results shown in the reports are indicative only and depend on the adopted methodology, data selection, parameters, assumptions, and the way risk and return measures are calculated. Actual results may differ materially from historical or simulated results.

The author may hold positions in the instruments discussed or may apply a similar approach in practice. The information contained in the reports may change without prior notice.

Methodology

TradingEdge.Pro's methodology describes a multi-step process for building and validating trading strategies, structured into two parts: strategy development and testing, and practical use. In the testing phase, a strategy is defined as a set of objective rules, validated through initial tests, optimised, and assessed for stability (robustness), and then evaluated using Walk-Forward Analysis. The detailed testing assumptions (including the instrument universe, in-sample/out-of-sample periods, data sources, transaction costs, and execution rules) are described in the "Testing Specification" document. The full methodology and metric definitions are available on the TradingEdge.Pro "Methodology" page.

Expansion Pivots v.1

Investment Strategy Testing Summary

The Expansion Pivots v.1 strategy is a swing trading technique developed by **Jeff Cooper** that takes advantage of **price breakouts in line with the main trend after a market correction** to the moving average. The main assumption of the strategy is that **the breakout is accompanied by an extended daily price range** compared to the previous days.

Although the logic of the strategy seems sound, <u>it has not even passed the initial test,</u> **because the number of test transactions is very low, which makes it impossible to draw reliable conclusions. Therefore, <u>it is not recommended to use it in real transactions.</u>**

Our goal is to have a strategy that remains **profitable and effective over a wide range of parameters,** because the market is a changing organism and the optimal parameters can change over different periods. <u>**I cannot** emphasize enough that for **a strategy to work** in real conditions, it must also work on **suboptimal parameters** and in **suboptimal conditions.**</u> In a word - **it must be stable** to changing market conditions.

I don't know who said these words, but they perfectly reflect the problem of many optimizations:

"I've never seen a strategy that didn't work in backtests."

We don't know the future, we don't know future market conditions, but if we know that our strategy **has historically generated acceptable results** in various market conditions and across various parameter ranges, then we are **one step ahead of other** market participants.

Contents

Step 1: Formulate an investment strategy

Expansion Pivots v.1 strategy was developed by Jeff Cooper as **a short-term swing trading system** that combines observation of **the daily price range with a support/resistance level set by a moving average.** Its goal is to allow the trader to capitalize on **a sharp breakout in price after a period of consolidation around that average** – indicating a possible continuation of the prevailing trend.

The strategy uses:

- **Daily Range Extension** – Today's range (high – low) must be the largest in the last few sessions;
- **Position relative to the moving average (SMA)** – the direction of the transaction depends on which side of the average the breakout candle closes;
- **Interaction with a moving average (SMA)** – the low (for longs) or high (for shorts) of today or the previous day must cross the SMA, which confirms that the move came from its immediate vicinity.

The strategy includes **both long (buy) and short (sell) positions,** depending on the position of quotes relative to the moving average (SMA). The key element is the precise setting of activating orders and **strict risk management through stop loss orders.**

Characteristics of the strategy and its strengths and weaknesses:

- **The use of a commonly monitored level** – SMA is a popular "benchmark" for institutions, which increases the credibility of signals.
- **Clear, unambiguous criteria** – three simple conditions (scope, closure, interaction with SMA) facilitate automation.
- **Potential for strong moves** – breakouts from consolidation around the SMA can generate dynamic, short-term trends.
- **Volatility Sensitivity** – the strategy requires a wide daily range, so during periods of market calm signals are infrequent or unreliable.
- **The need for ongoing observation** – the formation takes place in the short term and requires daily control of parameters.
- **Limited effectiveness in a sideways trend** – in the absence of a clear direction around the SMA, the strategy may generate a series of losses.

Expansion Pivots strategy uses simple but precise rules to allow traders to join in on the rapid price action after the market rebounds from the moving average. However, its effectiveness depends on sustained volatility and consistent risk management to minimize the impact of false signals.

Step 2: Define investment principles

Below is **the pseudocode** for the **Expansion Pivots v.1 strategy** on daily data:

1. **Calculation of indicators**
   a. **Daily range** – is the difference between the daily maximum (high) and minimum (low) of the last candle; measures the size of the movement within one session.
   b. **Largest Daily Range Over the Last X Sessions** – Determine the maximum value of the "Daily Range" over the previous X candles; this will serve as a reference point to determine whether the current move is unusually large.
   c. **SMA YY** – calculate the YY-day moving average of the closing price.
2. **Generating entry signals – long position (buy)**
   a. **Trend Conditions:**
      i. The current "daily range" must be greater than the largest range of the previous X sessions, which indicates a decisive breakout.
      ii. The closing price of the current candle should be above the SMA YY, confirming the advantage of buyers.
   b. **Expansion Pivot formation (long) –** the low of the current or previous candle crossed the SMA YY from above (i.e. was below the average), which signals that the breakout started directly in its zone of influence.
   c. **Entering the trade** – in the next session, set a buy stop order 1 tick above the high of the last candle, to be activated only if momentum continues.
   d. **Risk Management –** set a stop loss 1 tick below the low of the last candle, limiting your maximum loss in case of a false move.
3. **Generating entry signals – short position (sell)**
   a. **Trend Conditions:**
      i. The current "daily range" is larger than the largest range of the previous X sessions, which indicates a strong breakout to the downside.
      ii. The closing price of the current candle should be below the SMA YY, confirming the advantage of sellers.
   b. **Expansion Pivot formation (short)** – the high of the current or previous candle crossed the SMA YY from below (i.e. was above the average), which signals that the breakout started directly in its zone of influence.
   c. **Entering the trade** – in the next session, set a sell stop order 1 tick below the low of the last candle, to be activated only if the momentum continues.
   d. **Risk Management –** place a stop loss 1 tick above the high of the breakout candle, limiting your maximum loss in case of a false move.
4. **Closing a position** – if a stop loss has not been previously activated, close the trade at the opening ZZ of the session after entry, which limits exposure to adverse moves after the initial impulse.
5. **Daily monitoring**
   a. After each session, recalculate: "daily range", the largest X-session range and SMA YY to verify the current strategy parameters.

b. Once all conditions for a long or short position are met, set appropriate orders (buy stop or sell stop) for the next trading day.

The above rules have been described in a way that allows them to be directly converted into a script in the chosen testing platform, which ensures the accuracy of the historical simulation and the reliability of the test results.

Testing is performed assuming that **the risk of one position is 1.0% of total capital.**

Step 3: Conduct a preliminary test of the investment strategy

Below are some purchase and sale transactions that allow you to verify the following aspects:

- **Correctness of generated signals;**
- **Direction of opening position;**
- **Moment of opening a position;**
- **Position opening price;**
- **Moment of closing the position;**
- **Closing price of the position;**
- **Compliance of the transaction with the theoretical assumptions of the investment strategy.**

At this stage **it does not matter** whether the transactions are **profitable,** what **instrument was used** or whether they took place **recently** or **in the distant past.** The key is **to check whether the transactions are generated correctly** and in accordance with the assumptions described in the previous step.

The first transaction is on a GasOil futures contract. In October 2024, prices **were moving around the 100-day average,** indicating a dominant **downtrend** (quotes below the average, and the average itself is falling). Then the market formed **a large downward candle** (the second candle in the rectangle on the left), with **the largest price range (high-low) in the last 5 days.** The previous day's high candle (the first candle in the rectangle on the left) **fell above the 100-day average,** and today's close (the second candle) was below this moving average. **Therefore, all the elements necessary to initiate a short position have been met,** so the next day we set **a sell stop order one tick below the low of the largest candle.** This order was **activated the next day** (the third candle in the rectangle on the left) and **a defensive order was set** one tick above the high of the largest candle (red dot). **The system worked correctly.**

Quotes were falling slightly and **on the eleventh day the position was closed to the opening** (the rectangle on the right). Counting from the opening day, the position was active for ten days and closed on the eleventh day to the opening. **The system worked correctly.**

The second transaction is on a crude oil futures contract. In May 2024, prices **were moving around the 100-day average,** indicating a dominant **upward trend** (quotes above the average, and the average itself was

rising). Then the market formed **a large bullish candle** (the first candle in the rectangle on the left), with **the largest price range (high-low) in the last 5 days.** The low of this candle **also fell below the 100-day average,** and the close above this moving average. **Therefore, all the elements necessary to initiate a long position were met,** so the next day we set a **buy stop order one tick above the high of the largest candle.** This order was activated the next day (the second candle in the rectangle on the left) and **a defensive order** (red dot) was set one tick below the low of the largest candle. **The system worked correctly.**

On the fifth day from the opening of the position, **the quotes fell to the stop loss level and the position was closed at a loss** (the rectangle on the right). **The system worked correctly.**
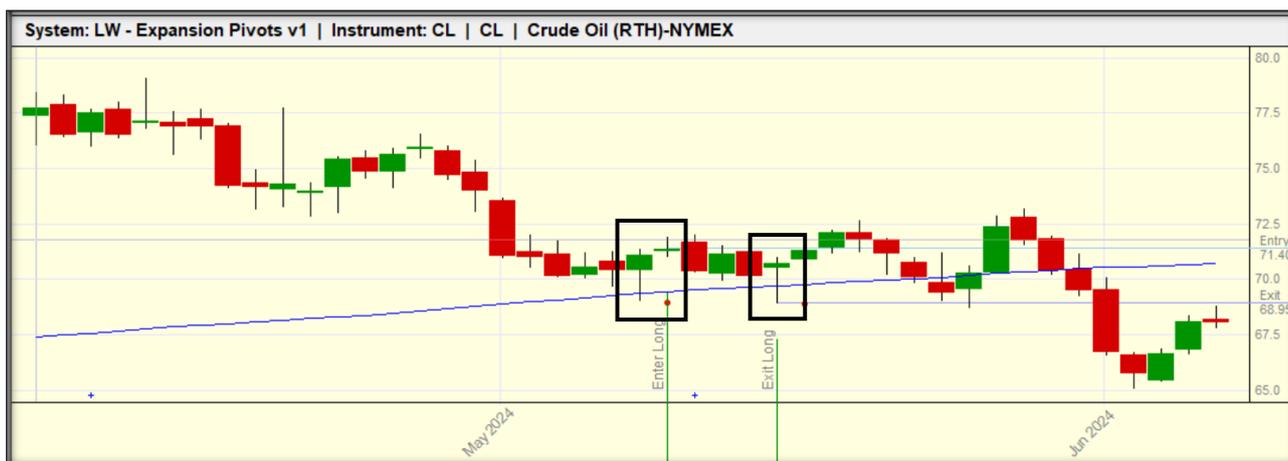

Once we are sure that the trades are generated correctly, we can proceed to the first test of the strategy on the full **in-sample data set.** These tests are performed on **the basic parameters,** which – according to my assessment – should correspond to the assumed goals of the strategy.

First of all, **we reject strategies that linearly lose capital.** If a strategy exhibits such a pattern, it is a clear signal that any parameter optimization does not make sense.

Our basic expectation is that the strategy generates **positive results,** even if they are at a low level.

The tested output parameters are:

- **The largest range (maximum – minimum) of daily price change:** 5 days;
- **Moving Average Length (SMA):** 100 days;
- **How to open a position:** buy/sell stop one tick above/below the high/low of the previous candle, which is the highest in 5 days (for a long/short position respectively);
- **Stop loss:** one tick below/above the low/high of the previous candle, which was the highest in 5 days (for long/short position respectively);
- **Closing a position:** 10 days after opening (11 days after opening);
- **Position direction:** long and short;
- **Position sizes:** corresponding to a risk of 1.0% of total capital.

The test result is shown below.

Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.
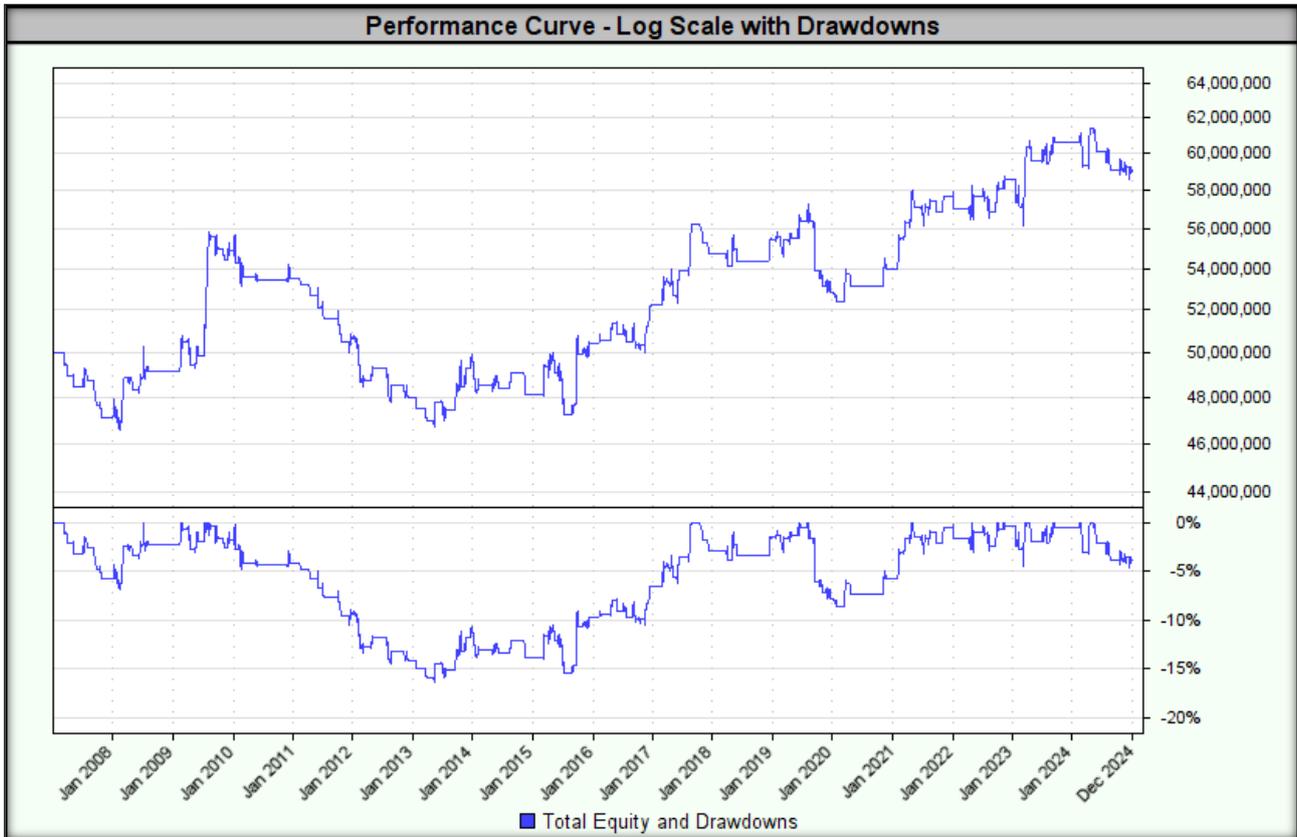

Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.

Indicators/Measures	Concluding a transaction at the opening price
CAGR%	0.9%
MAR Ratio	0.06
RAR%	1.1%
R-Cubed	0.05
Robust Sharpe Ratio	0.23
Max Drawdown	16.3%
Wins	45.9%
Losses	54.1%
Average Win%	1.28%
Average Loss%	0.91%
Win/Loss Ratio	1.41
Average Trade Duration (days)	10
Percent Profit Factor	1.20
SQN	0.24
Number of transactions	194

In summary, the system worked correctly and generates signals as expected. **However, although the tests on the output parameters are acceptable, the number of test transactions is very low (below 200). This**

means that even with satisfactory optimization results, the reliability of this strategy would remain low. At this stage, we are ending the tests and resigning from further development of the strategy.

Step 4: Optimization and assessment of investment strategy stability

1. **Stability across a wide range of optimized parameters**

The step was skipped due to **failure of the preliminary tests.**

2. **Monte Carlo simulation**

The step was skipped due to **failure of the preliminary tests.**

3. **Stability over a moving time window**

The step was skipped due to **failure of the preliminary tests.**

4. **Long/short stability**

The step was skipped due to **failure of the preliminary tests.**

5. **Stability in the portfolio of financial instruments**

The step was skipped due to **failure of the preliminary tests.**

6. **Money Management (Position Sizing)**

The step was skipped due to **failure of the preliminary tests.**

7. **Strategy Risk Management**

The step was skipped due to **failure of the preliminary tests.**

Step 5: Walk-Forward Analysis

The step was skipped due to **failure of the preliminary tests.**

Step 6: Using the strategy in real time

The step was skipped due to **failure of the preliminary tests.**
