The results presented may include historical simulations (backtests) and may not reflect all execution costs and constraints (including commissions, spreads, slippage, taxes, and liquidity limitations). Historical or simulated performance is not a guarantee of achieving similar results in the future.

Investing, especially in derivative instruments (e.g., futures, CFDs), involves high risk, including the risk of losing your entire invested capital and, in some cases, an obligation to provide additional margin.

These materials do not constitute an offer or solicitation to enter into any transactions. Do not copy the transactions or strategies presented. All investment decisions are made independently and at your own risk.

The results shown in the reports are indicative only and depend on the adopted methodology, data selection, parameters, assumptions, and the way risk and return measures are calculated. Actual results may differ materially from historical or simulated results.

The author may hold positions in the instruments discussed or may apply a similar approach in practice. The information contained in the reports may change without prior notice.

## Methodology

[TradingEdge.Pro's](#) methodology describes a multi-step process for building and validating trading strategies, structured into two parts: strategy development and testing, and practical use. In the testing phase, a strategy is defined as a set of objective rules, validated through initial tests, optimised, and assessed for stability (robustness), and then evaluated using Walk-Forward Analysis. The detailed testing assumptions (including the instrument universe, in-sample/out-of-sample periods, data sources, transaction costs, and execution rules) are described in the "[Testing Specification](#)" document. The full methodology and metric definitions are available on the TradingEdge.Pro "[Methodology](#)" page.

## Small Turtle v.2

### Investment Strategy Testing Summary

The **Small Turtle v.2** strategy is a **modification of version v.1**, inspired by Richard Dennis's "[turtle](#)" approach. Version **v.2** retains the same key parameters as v.1, but has been **optimized** using **The Grid Search technique**. The strategy itself is a **trend-following strategy** and uses **the Donchian channel** to define entry and exit points, as well as **ATR volatility** to determine position size, stop loss distances, and pyramiding steps.

However, while stability tests across a wide range of optimized parameters and Monte Carlo simulations passed, **the strategy failed the moving window test** – for the one-year period, only 18 of 27 periods resulted in a positive rate of return (**66.7% versus the minimum required 70%**). It is one of the tests performed as part of the robustness assessment, and failing to pass any of these tests means the strategy may not be sufficiently robust in a live environment.

I can't emphasize enough that for a strategy to work in real-world conditions, it must also work with suboptimal parameters and in suboptimal conditions. In short, **it must be stable** to changing market conditions.

I don't know who said these words, but they perfectly capture the problem of many optimizations:

*"I've never seen a strategy that didn't work in backtests."*

**We don't know the future**, we don't know future market conditions, but if we know that our strategy **has historically generated acceptable results** in various market conditions and across various parameter ranges, we are **a step ahead of other market participants**. However, **the Small Turtle v.2 strategy is not among them**.

## Step 1: Formulate an investment strategy

The **Small Turtle v.2** strategy originated from the classic "[turtle](#)" strategy, and compared to version v.1, **parameters were optimized** using **The Grid Search technique**. This is based on the observation that **the largest trends emerge after breakouts from long-term consolidations**. The system defines such a consolidation as the price range from the last, relatively long period (entry Donchian channel) and treats **a break above its upper boundary as a signal of the start or continuation of an uptrend** (long position), while **a break below its lower boundary as a signal of a downtrend** (short position).

At the moment of a **breakout, the first unit of a position is opened**, the size of which is selected so that a price movement by a specified multiple of the current volatility (measured by the ATR) in an unfavorable direction translates into a predefined percentage decline in the portfolio's value. If **the trend develops as expected**, a price movement towards the open position by a fixed portion of this volatility (e.g., a fraction of the ATR) **results in the addition of a second unit (pyramidization)**. A stop loss is maintained for the entire position at a fixed multiple of the ATR from the last entry level, allowing for pre-defined risk control at the level of a single transaction.

**The market exit occurs via a counter-movement breakout from the shorter Donchian channel** – the long position is closed when the price breaks down through the lower boundary of this channel, and the short position is closed when the price breaks up through its upper boundary. As a result, **the system gives back some profit at the end of the trend, but in return, it holds the position for most of the strong move**.

In **Small Turtle v.2** this logic remains unchanged, while the Donchian channel lengths, adopted ATR multiples and unit limits are treated as **parameters subject to optimization** in order to find stable, market-useful configurations.

The **Small Turtle v.2** strategy uses:

- **Donchian channel to open a position** – identifying a breakout from a long consolidation;
- **Donchian channel to close a position** – a signal of the end of a trend;
- **Average True Range (ATR)** – for determining position size, stop loss and pyramiding levels;
- **Pyramiding** – adding units towards profit, up to a maximum number of units;
- **Portfolio limits** – maximum number of units in correlated markets and in one direction.

**Characteristics of the strategy and its strengths and weaknesses:**

- **Strengths:**
  - **Natural trend-following system** – profits from rare, large trends;
  - **Fully mechanical** – no discretion, easy to test and automate;
  - **Pyramiding Winners** – Increasing your exposure when the market behaves as expected;
  - **Risk scaled by ATR** – adjusting the position to current volatility.
- **Weaknesses:**
  - **Poor performance in consolidations** – numerous false breakouts and short, losing trades;
  - **Delayed entries** – joining the trend only after a breakout from the range;

- **The need for broad diversification** – a single market may not generate profitable trends for a long time.

**The Small Turtle v.2** strategy, despite its relatively simple structure, requires the acceptance of longer periods of drawdowns and consistent adherence to money management principles, but in return it gives the opportunity to participate in large, directional price movements.

## Step 2: Determine investment principles

Below is the pseudocode for the **Small Turtle v.2 strategy** on daily data:

1. **Calculation of indicators:**
  - a. **Entry Breakout (XX days):**
    - i. **Upper Boundary:** Highest price of the last XX sessions;
    - ii. **Lower Boundary:** Lowest price of the last XX sessions.
  - b. **Exit Breakout (YY days):**
    - i. **Upper Boundary:** Highest price in the last YY sessions;
    - ii. **Lower Boundary:** Lowest price of the last YY sessions.
  - c. **ATR(20):** 20-day average true volatility range.
2. **Entry – long position (buy):**
  - a. **Entry condition:** the candle's high falls above the upper border of the 20-day Donchian channel.
  - b. Calculate the unit size so that a downward price movement of  $ZZ \times ATR(20)$  represents a 0.5% decline in the portfolio value.
  - c. Open your first long trade; set a stop loss  $ZZ \times ATR(20)$  below the entry price.
3. **Entry – short position (sell):**
  - a. **Entry condition:** the low of the candle falls below the lower border of the 20-day Donchian channel.
  - b. Calculate the unit size as in point 2b.
  - c. Open the first short unit; set a stop loss  $ZZ \times ATR(20)$  above the entry price.
4. **Pyramiding positions:**
  - a. If the price has moved towards profit by  $QQ \times ATR(20)$  since the last entry price, add another unit in the same direction (long/short).
  - b. Do not add more than 2 units per instrument (including the first one).
5. **Exiting a position:**
  - a. **Long position:** Close all units when the price falls below the lower border of the YY-day Donchian channel or when a stop loss is activated.
  - b. **Short position:** Close all units when the price rises above the upper border of the YY-day Donchian channel or when a stop loss is activated.
6. **Daily monitoring:**
  - a. Update Donchian channel values (XX and YY days) and ATR(20).
  - b. Check entry, pyramiding, exit conditions and compliance with portfolio limits.

The above rules are described in a way that allows them to be directly converted into a script in the chosen testing platform, which ensures the accuracy of the historical simulation and the reliability of the test results.

The tests are carried out assuming that the risk of one position is **0.5% of the total capital**, with the stop loss order placed at  **$ZZ \times ATR(20)$  from the position opening point**.

### Step 3: Pre-test your investment strategy

Below are some purchase and sale transactions that allow you to verify the following aspects:

- **Correctness of generated signals;**
- **Direction of opening a position;**
- **Moment of opening the position;**
- **The opening price of the position;**
- **Moment of closing the position;**
- **Closing price of the position;**
- **Compliance of the transaction with the theoretical assumptions of the investment strategy.**

At this stage, **it doesn't matter** whether the trades are **profitable**, what **instrument was used**, or whether they occurred **recently** or **in the distant past**. The key is **to verify that the trades are generated correctly** and in line with the assumptions described in the previous step.

**The first trade was executed on a futures contract for the Nasdaq 100 index.** At the end of April 2013, **the price broke out above the long-term Donchian channel (100 days)**, which, in accordance with the Small Turtle v.2 strategy, **generated a signal to open a long position** (candle marked 1). The system thus opened **the first long unit**, setting the initial **stop loss at a distance of  $2.5 \times \text{ATR}(20)$**  below the entry level (red dots on the chart). In the following days, the market continued its upward movement; when **the price moved up  $1 \times \text{ATR}(20)$**  from the first entry, **the system added the second — and last — allowable unit of the position** (candle marked 2). **The protective stop for the entire position** was then adjusted to remain **approximately  $2.5 \times \text{ATR}(20)$**  from the last entry level.

According to the Small Turtle v.2 strategy rules, **a long position is held as long as the price remains above the lower boundary of the shorter Donchian channel (30 days) or the stop loss level is not reached.** At the end of June 2013, a strong downward correction occurred; **one of the large candlesticks** (marked with a rectangle) **broke down the lower boundary of the exit channel**, which generated a signal to close the position. **Both long units were closed on a sell stop order.** The  $2.5 \times \text{ATR}(20)$  stop loss level remained intact throughout the transaction, and the position was closed precisely when the price crossed the exit channel. **The system worked correctly.**

The second trade was executed on a soybean futures contract. In early September 2008, the price broke down the long-term Donchian channel (entry), which, in accordance with the Small Turtle v.2 strategy, generated a signal to open a short position (candle number 1). The system opened the first short unit, setting an initial stop loss at a distance of  $2.5 \times \text{ATR}(20)$  above the entry level (red dots above the price). In the following days, the market continued its downward movement; when the price moved down  $1 \times \text{ATR}(20)$  from the initial entry, the system added the second —and last—allowable short unit (candle number 2). The protective stop for the entire position was then adjusted to remain approximately  $2.5 \times \text{ATR}(20)$  from the last entry level.

According to the Small Turtle v.2 strategy, a short position is held as long as the price remains below the upper boundary of the shorter Donchian channel (exit channel) or the stop loss level is not reached. At the end of December 2008, the market entered a stronger uptrend; one of the larger candles (marked with a rectangle) broke above the upper boundary of the exit channel, which generated a signal to close the position. Both short units were closed with a buy stop order. The  $2.5 \times \text{ATR}(20)$  stop loss level remained intact throughout the transaction, and the position was closed precisely when the price crossed the exit channel. The system worked correctly.

Once we are sure that the transactions are generated correctly, we can proceed to the first test of the strategy on the full **in-sample data set**. These tests are conducted on **baseline parameters** that, in my opinion, **should align with the strategy's stated goals**.

First, **we reject strategies that linearly lose capital**. If a strategy exhibits this pattern, it's a clear signal that any parameter optimization is pointless.

Our basic expectation is that the strategy generates **positive results**, even if they are at a low level.

Tested base parameters:

- **Entry Breakout (days):** 100;
- **Exit Breakout (days):** 30;
- **ATR (days):** 20;
- **Stop loss:**  $2.5 \times \text{ATR}(20)$ ;
- **Pyramiding (Unit Add):** every  $1.0 \times \text{ATR}(20)$ ;
- **Max units in one instrument:** 2;
- **Position sizing method:** Fixed Fractional, 0.5% of capital per unit;
- **Position direction:** long and short.

The test result is shown below.

*Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.*

Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.

Indicators/Measures	Concluding a transaction at the opening price
CAGR%	12.9%
MAR Ratio	0.48
RAR%	12.7%
R-Cubed	0.24
Robust Sharpe Ratio	0.55
Max Drawdown	26.8%
Wins	32.3%
Losses	67.7%
Average Win%	1.03%
Average Loss%	0.33%
Win/Loss Ratio	3.07
Average Trade Duration (days)	56
Percent Profit Factor	1.47
SQN	1.05
Number of transactions	2590

In summary, the system is working properly and generating signals as expected. Furthermore, tests on the baseline parameters yielded satisfactory results. We can now move on to the most interesting stage of creating an investment strategy – **optimization and stability**.

## Step 4: Optimizing and assessing the stability of the investment strategy

This stage of strategy development and testing is crucial because it determines how effective the strategy will be in real-world conditions. I cannot emphasize enough that for a strategy to work in real-world conditions, it must also perform under suboptimal parameters and conditions. In short, it must be stable to changing market conditions.

I don't know who said these words, but they perfectly capture the problem of many optimizations:

*"I've never seen a strategy that didn't work in backtests."*

My goal is not to find optimal parameter values – my goal is to find a wide range of parameters for which the strategy will generate acceptable results. We don't know the future, we don't know future market conditions, but if we know that our strategy has historically generated acceptable results in various market conditions and across various parameter ranges, then we are one step ahead of other market participants.

What parameters to choose for the next period is the topic of consideration in Step 5, "Walk-Forward Analysis", but before we get to that, we need to know whether our strategy is even stable.

### 1. Stability across a wide range of optimized parameters

This version of the Small Turtle v.2 strategy assumes optimization of the parameters proposed by the strategy's creator, Richard Dennis. We will optimize using the Grid Search method, which involves fully optimizing all specified parameters by creating a wide range of possible combinations. Our goal is to find parameter ranges that will keep the strategy stable (robust), allowing us to assess its suitability in real-world market conditions.

The key criterion for assessing stability is that all test results must demonstrate a positive MAR, and the maximum drawdown must not exceed 250% of the drawdown for the result with the highest MAR. If any test produces a negative MAR, or if the drawdown exceeds 250% of the drawdown for the result with the highest MAR, the strategy is rejected entirely.

In the first step, we test the stability of the parameters on in-sample data. To do this, we define ranges of parameter values so that the ratio of the highest to lowest value of the range is at least 150%.

In the tested strategy, the ranges defined in this way are:

- **Entry Breakout (days):** range 80-140 (step: 5);
- **Unit Add (ATR):** range 0.5-1.0 (step: 0.5);
- **Stop (ATR):** range 2.0-3.0 (step: 0.25);
- **Exit Breakout (days):** range 25-40 (step: 1).

Other parameters remain unchanged.

The lowest MAR value of 0.24 was achieved for the following parameters:

- **Entry Breakout (days):** 80;

- **Unit Add (ATR): 1.0;**
- **Stop (ATR): 2.75;**
- **Exit Breakout (days): 26.**

*Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.*

In summary, the strategy passed the stability test over a wide range of optimized parameters on in-sample data because:

- All test results showed a positive MAR value – which indicates the stability of the strategy in various market conditions.
- The maximum drawdown did not exceed 250% of the drawdown value for the result with the highest MAR (38.5% vs. 28.0%) – which means an acceptable risk of deep capital drawdowns.

Heatmaps for the tested ranges are shown below.

After passing the stability tests on **in-sample data**, it is time perform the same procedure on **out-of-sample data**. For this purpose, we use **the same range of parameters** as on in-sample data:

- **Entry Breakout (days):** range 80-140 (step: 5);
- **Unit Add (ATR):** range 0.5-1.0 (step: 0.5);
- **Stop (ATR):** range 2.0-3.0 (step: 0.25);
- **Exit Breakout (days):** range 25-40 (step: 1).

Other parameters remain unchanged.

The lowest MAR value of 0.03 was achieved for the following parameters:

- **Entry Breakout (days):** 125;
- **Unit Add (ATR):** 0.5;
- **Stop (ATR):** 2.00;
- **Exit Breakout (days):** 25.

*Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.*

Below is a graph of the equity curve for **the strategy with the lowest MAR**.

*Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.*

The highest MAR value of 0.37 was achieved for the following parameters:

- **Entry Breakout (days):** 90;
- **Unit Add (ATR):** 0.5;

- **Stop (ATR): 2.75;**
- **Exit Breakout (days): 38.**

The highest MAR value was accompanied by a drawdown of 24.8%.

*Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.*

In summary, the strategy passed the stability test over a wide range of optimized parameters on out-of-sample data because:

- All test results showed a positive MAR value – which indicates the stability of the strategy in various market conditions.
- The maximum drawdown on out-of-sample data did not exceed 150% of the maximum drawdown value on in-sample data (36.3% vs. 38.5%) – which means an acceptable risk of capital drawdown.
- The decrease in the maximum MAR value on out-of-sample data was less than 50% compared to the in-sample test results (0.52 vs. 0.60) – indicating that the strategy can achieve good results in a variety of market conditions.

Heatmaps for the tested ranges are shown below.

Once the stability test has passed across a wide range of optimized parameters, we can proceed to **stability testing using Monte Carlo simulation**. The conditions for passing this test are similar to those required in the step above.

## 2. Monte Carlo simulation

**Monte Carlo simulation** involves running multiple simulations to examine how a strategy might perform under various market scenarios. A key goal of this method is to assess the potential **drawdown** of an optimized strategy. **Monte Carlo simulation** better reflects possible equity curve fluctuations and the depth of potential **drawdown**, allowing for a more realistic risk assessment. It also provides an ideal opportunity to

compare **the drawdown** obtained in tests on optimized parameter ranges with the results of **the Monte Carlo simulation**, using a **99% confidence interval**.

A strategy considered to be **stable (robust)** should achieve a **drawdown** in a **Monte Carlo simulation** that does not exceed **250% of the drawdown size from total tests in-sample and out-of-sample** (for parameters optimized on IS data). Furthermore, the **MAR indicator** should remain positive within the chosen confidence interval.

For data covering the period from **January 1, 1998 to December 31, 2024**, a **Monte Carlo simulation** was performed using **optimal strategy parameters**. The Monte Carlo simulation was performed **100,000 times**, testing **the variant with replacement (more conservative)**, and the **confidence interval** was set to **99%**.

The **sample-replacement simulation** are presented below.

*Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.*

- **CAGR%** – In 99% of simulations achieved a **rate of return equal to or higher than 2%**.
- **Drawdown** – 99% of simulations achieved a **drawdown of 78% or less**. For parameters optimized on in-sample data, the drawdown was 32.9%.

The strategy's stability criteria were met, as **the drawdown in the Monte Carlo simulation** did not exceed **250% of the drawdown** value from tests with **optimized parameters**. Furthermore, the **MAR indicator** remained positive in **99%** of tests, which was also a condition for the strategy's stability.

**Now that we know** that the strategy is **stable** across **wide ranges of data** and a **changing environment**, it is time to test its **stability** over **different time periods**.

### 3. Stability over a moving time window

Rolling window stability testing involves **evaluating one-year and three-year returns in time windows that move one year** apart (for both in-sample and out-of-sample data). This process involves **applying strategy parameters optimized for the in-sample data**, setting a one-year or three-year trading window, and then advancing it by one year.

We then analyze what proportion of these one- and three-year periods showed positive returns. **A strategy considered robust should achieve profitable results in at least 70% of the one- and three-year periods.**

For data covering the period from **01/01/1998 to 31/12/2024**, testing of **optimized parameters** was carried out on a **moving data window**.

**Two variants of test windows** were tested:

- **Annual testing window (365 days)**, tested **every 365 days** – this means that **we measure the annual rate of return every year**.
- **Three-year testing window (1095 days)**, tested **every 365 days** – this means **we measure the three-year rate of return every year**.

Test results for a **one-year (365/365) test window** are shown below.

*Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.*

Test results for a three-year testing window (1095/365) are shown below.

Historical or simulated results do not guarantee that similar outcomes will be achieved in the future.

Test Start Date	End Balance	CAGR%	MAR	Sharpe	Ann. Sharpe	Max TE DD	Longest DD	Trades	R3	RAR [%]	%PF	Expectancy	Ruin	Long

In both cases, success is the completion of at least 70% of the periods (both 365-day and 1095-day) with positive returns.

- For the one-year test window (365/365): 18 out of 27 periods ended with a positive rate of return (67%).
- For the three-year test window (1095/365): 25 out of 25 periods ended with a positive rate of return (100%).

Therefore, the test of the strategy's stability on a moving data window **was not passed and we are terminating further testing of the strategy.**

#### 4. Long/short stability

The step was omitted due to failure of previous stability tests.

**5. Stability in the portfolio of financial instruments**

**The step was omitted** due to failure of previous stability tests.

**6. Money Management (Position Sizing)**

**The step was omitted** due to failure of previous stability tests.

**7. Strategy Risk Management**

**The step was omitted** due to failure of previous stability tests.

## Step 5: Walk-Forward Analysis

**The step was omitted** due to failure of previous stability tests.

## Step 6: Using the strategy in real time

**The step was omitted** due to **failure of previous stability tests.**
